

KISTLER

measure. analyze. innovate.

Acceleration

**Providing Quick,
Accurate and Reliable
Measurements**

Kistler Has a Wide Acceleration Product Offering

This catalog provides comprehensive information on all Kistler products for the measurement of:

- Acceleration
- Shock
- Angular Acceleration
- Acoustic Emission
- Dynamic Force for Modal Investigations

The overview of the Kistler range is followed by detailed information on our products in tabular form and a presentation of the company as a whole.

Acceleration brochures focusing on specific applications, such as space and aerospace or automotive, are available.

At Kistler, measuring instruments are used in a wide variety of fields. Application specific brochures are also available for the following:

- Engines
- Vehicles
- Manufacturing
- Plastics Processing
- Biomechanics

The aim of this catalog is to assist you in selecting the right choice from our wide range of products and to suggest ways of optimizing your application.

Please contact us at info@kistler.com for more information, product catalogs, application brochures, data sheets, or to speak with a local Kistler representative.

We wish you every success with Kistler measurement instruments and thank you for your confidence and interest.

K-Beam®, K-Shear®, PiezoBeam®, PiezoStar® and Piezotron® are registered trademarks of Kistler Holding AG. Ceramic Shear and Picotron are products of Kistler Holding AG.

Kistler Measures Acceleration

Accelerometers are used in every avenue of the dynamic test environment and Kistler has developed families of products covering this expansive range of applications. From ultra-low motions encountered in wafer fabrication technology to shock spectra reconstruction experienced in pyrotechnic separation event studies and everywhere in between, an optimal sensor solution is available. Static events are captured with the K-Beam® static and low frequency product offerings. Very high frequency activity is routinely measured using any of several miniature piezoelectric single-axis or triaxial types. Many sensing technologies including piezoceramic, natural quartz and variable capacitance approaches have been extensively explored and are employed as needed to accommodate the demands of the application.

Some applications include:

Structural Testing

Mechanical devices, assemblies, and constructions of all types are investigated using accelerometers to measure their dynamic response when subjected to a known input. The deformation pattern, when the specimen experiences resonance, can be computed from the measured data.

Known as 'Experimental Modal Analysis' (EMA), this field of study often uses a member of the PiezoBeam® family or Ceramic Shear family where their general characteristics have been adapted to accommodate most requirements of common tests. Typical highlighted features include high output from a low-weight sensor, ground isolated, and an inexpensive package providing an economical solution for large channel count application.

Aerospace and Military

Very demanding applications are encountered in the military and aerospace industry where any error may present a life-threatening situation. This category also covers a tremendous range of applications and nearly all accelerometer product offerings have been used in these important investigations.

Flutter testing, rocket launch pad dynamics, aircraft EMA, ammunition investigations, helicopter rotor reactions, etc., are a few of the common measurements performed.

Automotive/Transportation

Ride quality has been receiving tremendous attention in recent years. New vehicle designs are presenting less noise to the occupants and the subtle details of the intricacies of road/wheel interaction, bump & jar response, and the overall feel of the ride are important to even the common customer. The K-Beam® family covers the low to mid frequency range of many investigations and the many piezoelectric offerings extend into the higher frequency areas of interest.

Civil Engineering

Very low frequency activity is of interest when studying extremely large structures, such as bridges, buildings or dams. These specimens require DC capable accelerometers since most dynamic activity is in the very low frequency realm often in the range of a few hertz. The K-Beam® product family is commonly used to measure vibration and acceleration in this arena.

Environmental Stress Screening

Computer components, automotive electronics, and miniature mechanical assemblies are often exposed to an aggressive life test or actual functional tests under extreme environmental conditions. This may involve multiple impact drop testing or wide range thermal cycling and many of the K-Shear® product offerings have been tailored to survive and perform extremely well even under incredibly abusive conditions. The M5- and M8- suffixes provide extreme high and low temperature capabilities respectively while the shear shock Types 8742 and 8743 survive after numerous exposure to high-level cyclic inputs.

Kistler Measures Acceleration

Remarkable lifetime under any condition

Precise, ultra-low frequency, measurements are common using a K-Beam® solution

Modal studies easily accomplished using an array of inexpensive accelerometers

Tilt and comfort controlled using K-Beam® feedback

Space quality measurements are routine

Aircraft issues measured accurately with K-Beam® family

Harsh environments present negligible concern when using K-Shear® accelerometers

On-site or factory calibration solutions available

Kistler Piezoelectric Sensor Technology Solutions

Most Kistler sensors rely on a quartz force link consisting of thin quartz plates, disks/washers or rods. The sensor is connected to an electronic device for converting the charge signal into a voltage signal proportional to the mechanical force. The conversion is made either by means of a separate charge amplifier or an impedance converter with coupler, typically integrated into the sensor. Kistler relies mainly on the 'Piezoelectric Theory' (see definition on pages 55 ... 58) for measuring dynamic forces in assembly and testing.

Kistler offers a variety of sensor technologies: Capacitive, Charge, and Voltage (IEPE). Examples of these sensor types are provided below.

Each offers unique application solutions applications tailored to your specific needs. For a detailed explanation of these Kistler sensor types, please reference pages 55 ... 59.

MEMS Capacitive Sensor Solutions

Type 8315A, Single-Axis
MEMS Capacitive Accelerometer

Type 8395A, Triaxial
MEMS Capacitive Accelerometer

Advantages

of Kistler Capacitive Accelerometers:

- Measures DC
- Built-in low-pass filters
- Repeatable measurements

Applications:

- Low frequency vibrations
- Ride quality
- Aerospace structural analysis
- Orientation

Charge Output Sensor Solutions

Types 8202 / 8203, Single-Axis
Charge Output Accelerometers

Types 8290, Triaxial
Charge Output Accelerometer

Advantages

of Kistler Charge Accelerometers:

- Adjustable time constant
- Adjustable sensitivity
- Can apply filters with charge amp
- Wide temperature range

Applications:

- Shock
- High amplitude vibrations
- Vehicle or environmental testing
- High temperature

Voltage (IEPE) Sensor Solutions

Type 8704, Single-Axis
Voltage Mode (IEPE) Accelerometer

Types 8763, Triaxial
Voltage Mode (IEPE) Accelerometer

Advantages

of Kistler IEPE Accelerometers:

- Built-in charge-to-voltage converter
- Ideal for dynamic measurements
- Does not require low noise cables
- Long cable length
- TEDS option available

Applications:

- Vibrations
- Vehicle or environmental testing
- Modal analysis

Kistler Calibration

Kistler accelerometers are calibrated in the factory and delivered with a calibration certificate. The reference sensors are cross-referenced to national standards. Kistler operates a NIST traceable calibration center and the calibration laboratory No. 049 of the Swiss Calibration Service for the measurands: force, pressure, acceleration and electric charge.

Kistler and some of its group companies offer a recalibration service and the company records in its archives the details of when and how often a particular sensor was calibrated.

Kistler offers an on-site service for recalibrating built-in sensors, thereby minimizing downtimes. In addition, Kistler offers a wide range of instruments for use in calibration laboratories.

Our calibration service receives the highest marks. The calibration of your instruments, manufactured by Kistler or someone else, is performed with quality care and precision. Our standard prompt service is exceptional. Kistler operates numerous calibration laboratories accredited to ISO/IEC 17025.

Kistler Calibration Service Description by Type Number

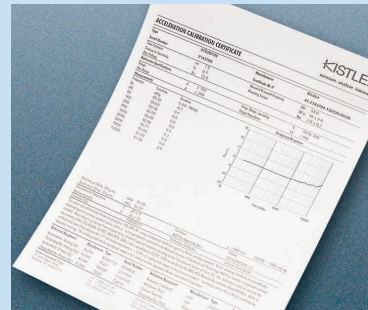

Type	Calibration Service Description
9953AnM	Recalibration: n-axis accelerometers, Swept sine excitation, calibration at intermediate frequencies
9950AnM	Accredited calibration: n-axis accelerometers, Swept sine excitation, calibration at intermediate frequencies, calibration certificate conforms to ISO 17025
9953AnL	Recalibration: n-axis accelerometers, Swept sine excitation, calibration at low frequencies
9950AnL	Accredited calibration: n-axis accelerometers, Swept sine excitation, calibration at low frequencies, calibration certificate conforms to ISO 17025
9953AnX	Recalibration: n-axis accelerometers, shock calibration

PiezoStar® IEPE Accelerometers

A New Dimension in Sensor Technology

Miniaturization and temperature stability

For more than 40 years, Kistler has been developing and manufacturing piezo-electric sensors that are used to measure pressure, force and acceleration under extreme conditions. Presently, sensor elements are increasingly manufactured from new types of crystals.

Market trends toward miniaturization and stability at higher operating temperatures have resulted in a need for new types of crystals. Resultingly, research has been conducted for over ten years in cooperation with universities and institutes throughout the world to investigate new crystal compounds and develop growing processes. The fruit of this research is the PiezoStar family of crystals, which exhibit unique performance to improve the data quality for physical measurements. Marking 10 years of in-house crystal production is a third expansion of crystal manufacturing capacity. This material is the key to improved sensor elements for pressure, force and acceleration sensors extending higher accuracy and providing better sensitivity at higher working temperatures.

Kistler has optimized the PiezoStar crystal elements for use in piezoelectric and IEPE (Integrated Electronics Piezo-electric) sensors, thus strengthening its technological edge in sensor technology. PiezoStar crystals currently reside within many Kistler sensors. In particular, Kistler PiezoStar (IEPE) accelerometers use shear cut seismic elements in combination with high temperature internal hybrid microelectronic impedance converters to provide industry leading stability with temperature. PiezoStar IEPE accelerometers generate up to 3x higher voltage sensitivity compared to quartz – which is ideal for miniaturization.

PiezoStar® IEPE Accelerometers

Vibration testing for dynamic temperature applications

PiezoStar accelerometers provide highly stable measurements with temperature. This 'out-of-the-box' solution requires no additional installation tasks compared to other accelerometers. External temperature compensation is a time consuming process requiring temperature and sensitivity measurement in order to characterize variations with temperature. Common compensation methods use either a look-up table or a polynomial based correction. PiezoStar accelerometers do not require any additional measurements or calculations as the vibration sensing technique has inherent sensitivity stability with temperature.

Kistler's PiezoStar element design provides a wide operating frequency range together with extremely low sensitivity to temperature. This technology allows accelerometers to operate at temperature ranges from $-55 \dots 165 \text{ }^\circ\text{C}$, providing stability especially in dynamic operating temperatures. Kistler PiezoStar crystals, combined with high gain integral hybrid microelectronics, provide very low sensitivity variation over the operating temperature range in comparison to other IEPE accelerometer materials such as quartz and ceramics. As shown in Fig. 1, PiezoStar IEPE accelerometer sensitivity deviation with temperature results in over 10 times less error due to temperature compared with typical IEPE accelerometer types.

In-house crystal production

PiezoStar® Accelerometer Features

- High voltage sensitivity (up to 3x higher than quartz) with inherent benefits for miniaturization
- Low temperature dependence, nearly eliminating sensitivity temperature errors, thus providing a more accurate measurement
- PiezoStar is a rigid material providing high stiffness to optimize accelerometer seismic element resonance frequencies and provide wide, usable frequency ranges.
- Wide operating temperature range, voltage mode (IEPE) operation from $-55 \dots 165 \text{ }^\circ\text{C}$; special products satisfy cryogenic operation to $-196 \text{ }^\circ\text{C}$
- The PiezoStar growing process is reproduced on an industrial scale.
- Tested and successfully used in demanding applications for acceleration, pressure and force measurement

PiezoStar® IEPE shear accelerometer

PiezoStar® IEPE Accelerometers

PiezoStar® IEPE Accelerometer Applications

Applications include automotive under the hood and under the vehicle testing, aviation/aerospace applications and environmental/product testing, which require

dynamic temperature testing. PiezoStar accelerometers are designed with hermetic titanium construction and a variety of mounting, electrical connector orientations and ground isolation options. The accelerometer requires an IEPE compatible DC power supply to power the sensors.

Such power supplies are available as stand-alone equipment, like Kistler

Types 5134B and 5118B2, or can be integrated with modern data acquisition equipment.

Applications

Vehicle R&D

Vehicle NVH (Noise Vibration Harshness) has requirements to mount accelerometers on the engine, powertrain, mounts, chassis and underbody. Vehicles, subsystems and components are exposed to a variety of environments to validate the design. Examples include dyno-testing, road testing at proving grounds in hot and cold locations, and durability testing. Such testing validates the reliability and structural performance over the operational environments.

Environmental and product testing

Environmental and product testing exposes products to a full range of conditions, including temperature, vibration/shock and humidity, to validate reliability during development/production. Control and response accelerometers are exposed to these extreme conditions, as well as the equipment under test. PiezoStar accelerometers minimize temperature errors and provide accurate control and vibration measurements.

Aviation/aerospace R&D and flight test

Flight test has requirements for wide temperature ranges from hot desert to high altitude locations. Such testing validates the reliability and structural performance over the operational envelope. PiezoStar accelerometers minimize temperature measurement errors for system, sub-system and component level testing.

Special application:

Cryogenic structural testing

Standard PiezoStar IEPE accelerometers are well known for -55 ... 165 °C operation. A special 50 g, 100 mV/g model, Type 8703A50M8, provides operation up to -196 °C. Testing of space-based structures uses low level excitations and requires a high dynamic range measurement. Type 8703A50M8 has 8.8 grams of mass and over 90 dB dynamic range, providing precise measurement is taken.

Type 5125C...		
Technical Data		
Sensor excitation current	mA (±10 %)	±4,3
Frequency response	kHz	Default: 50 ... 1 000
Output 1	mA	4 ... 20
Output 2	VDC RMS	0 ... 10
Output 3		Alarm Switch
Output 4	VAC, Raw AE	0 ±5
Gain		Default: 10 (adjustable by user = 1 or 100)
Power	VDC	18 ... 35
Operating temp. range	°C	-40 ... 80
Dimensions (WxHxD)	mm	133x86x105
Connector	type	cable gland pigtail or conduit adaptor
Mass	grams	1 100
Data sheet		5125C_003-119 5125C_000-120

Properties	High sensitivity and wide frequency range, inherent high-pass characteristic, robust, suitable for industrial use (high temp., hermetically sealed, IS/ATEX options available), ground isolated, braided or non-braided integral cable available; CE compliant	
Application	Measurement of high energy surface waves above 50 kHz in the surface of metallic components, structures or systems. Detection of flow perturbation, leakage, plastic deformation of materials, crack formation, fracturing, friction and fatigue. Non-destructive testing, as well as permanent online monitoring of continuous processes for conditional and preventative maintenance. ATEX certifications option allows for usage in hazardous environments, such as processing industries applications where explosive gas and dust is always present.	
Accessories	Magnetic clamp: Type 8443B	
Versions	Type 8152Cxyy00... : PFA cable (yy = length in m) Type 8152Cxyyyy... : Braided cable (yy = length in m) Type 8152C.....0: Non-Intrinsically Safe Type 8152C.....1: Zone 0 Certification in Europe & N.A. Properties		Simple to operate, AC coupled, reverse polarity protection; use with low impedance Piezotron® sensors with built-in electronics; CE compliant	Turn a digital multimeter into a hand-held relative vibration measurement system or verify sensor and cable integrity with this portable, low cost, battery operated coupler	Provides constant current excitation, monitors condition of sensors and cables; 3,5" digital LCD display AC-DC or battery powered; CE compliant	Selectable gain and low-pass, plug-in filters, panel selectable, high-pass filtering, exclusive "Rapid Zero" feature AC-DC or battery powered; CE compliant
Application		Provide DC power to sensors that contain miniature impedance converting circuits and to couple the signal generated in each to an electronic measurement instrument	Transforms an ordinary digital voltmeter into a simple measuring tool; ideal for troubleshooting sensors, cable or vibration problems in an industrial environment for low impedance sensors	Power and monitor Piezotron® low impedance sensors	Powering low impedance sensors where test conditions require flexible signal conditioning
Accessories		Cable: Types 1761B, 1761C		AC-DC power adapter: Type 5752	AC-DC power adapter: Type 5752 Panel mounting kit: Type 5702 Plug-in low-pass filters: Types 5326A..., 5327A...
Versions			Type 5110S1 kit: with case, mounting wax and 9 V battery	Type 5114: 9 V alkaline battery Type 5114S1: 9 V alkaline battery, 115 VAC power adapter and carrying case Type 5114S1(E): as S1 with 230 VAC power adapter

Calibration and Test Equipment

Reference Shakers, Insulation Tester and HSU-Nielsen Test Kit

Type 8921B...			
Technical Data		Type	
Reference frequency	Hz	8921B01	8921B02
Amplitude			
Acceleration r_{ms} , $\pm 3\%$	g	1	selectable: 15,92 ... 1 280
Velocity r_{ms} , $\pm 3\%$	mm/s	10	selectable: 0,102 ... 2,039
Displacement r_{ms} , $\pm 3\%$	μm	10	1 ... 200
Maximum load	grams	600	500
Operating temp. range	$^{\circ}\text{C}$	-10 ... 55	-10 ... 55
Operating time	hours	5	5
Power supply		built-in battery; rechargeable	built-in battery; rechargeable
Battery charger			
Input voltage	VAC	100 ... 240	100 ... 240
	Hz	50/60	50/60
Output voltage	VDC	11 ... 18	11 ... 18
Output current	A	<1	<1
Dimensions (HxWxD)	mm	100x100x120	100x100x120
Data sheet		8291B_003-090	8291B_003-090

Properties	Test measurement system integrity; convenient self-contained and portable; rechargeable battery; tests sensors up to 500 grams; CE compliant; Type 8921B02 has selectable reference frequency and amplitudes
Application	The Type 8921B... reference shaker can be used to confirm sensitivity of acceleration, velocity and displacement sensors.
Accessories	Stud 10-32 to M5, Type 8451 Stud 1/4-28 to M5, Type 8453
Versions	With power plug 110 ... 230 VAC

Type KIG-4930A	
Technical Data	
Contains:	2 pencils with 0,35 mm and 0,5 mm; 2 H leads with specific plastic tip adaptor

Application	Generating a sharp pulse of low amplitude according to HSU-Nielson Test per ASTM Std. E976; allows for calibration of acoustic emission sensors or for resonance frequency determination of a mounted acceleration sensor
--------------------	---

Type 5493		
Technical Data		
Number of channels		1
Measuring ranges FS	Ω	$10^{11} \dots 4 \times 10^{13}$
Measuring voltage	V	5
Max. parallel capacitance (cable length)	nF nF	10 100
Measurement display		logarithmic
Power supply (battery)	VDC	9
Input signal	type/ connector	BNC neg.
Dimensions (LxWxH)	mm	36x81x150
Connector	type	pigtails
Mass	kg	0,29
Degree of protection to IEC/EN 60529		IP50
Data sheet		5493_000-354

Properties	Small, robust service device for measuring high insulation resistance on the spot; low measuring voltage of 5 V, logarithmic indication avoids the need for range switching, automatic switch-off; CE compliant
-------------------	---

Application	Battery-powered tester ideal for routine and field checking of piezoelectric sensors, charge amplifiers and cables
--------------------	--

Accessories

Mounting

Common accessories extend the flexibility of the accelerometer families, often adapting to less than optimal conditions. For instance, the variety of adhesive mounting pads provide ground isolation while permitting a reasonable attachment in situations where tapping a threaded hole is unacceptable.

A series of magnet mounts provide an alternate solution if the structure is a ferrous material. Also included in this section are a variety of conversion studs to accommodate a previous mounting site to a different accelerometer with different threads. Mounting cubes provide a means of obtaining accurate orthogonal measurements at a reasonable cost.

Magnetic Mounting Base – See Data Sheet 8400_000-281 for More Information

Piezoelectric Theory

Piezoelectric Effect

Although the piezoelectric effect was discovered by Pierre and Jacques Curie in 1880, it remained a mere curiosity until the 1940's. The property of certain crystals to exhibit electrical charges under mechanical loading was of no practical use until very high input impedance amplifiers enabled engineers to amplify their signals. In the 1950's, electrometer tubes of sufficient quality became available and the piezoelectric effect was commercialized.

Walter P. Kistler patented the charge amplifier principle in 1950 and gained practical significance in the 1960's. The introduction of highly insulating materials such as fluoropolymer and thermosetting plastic greatly improved performance and propelled the use of piezoelectric sensors into virtually all areas of modern technology and industry.

Piezoelectric measuring systems are active electrical systems. That is, the crystals produce an electrical output only when they experience a change in load. For this reason, they cannot perform true static measurements. However, it is a misconception that piezoelectric instruments are suitable for only dynamic measurements. Quartz transducers, paired with adequate signal conditioners, offer excellent quasi-static measuring capability. There are countless examples of applications where quartz based sensors accurately and reliably measure quasi-static phenomena for minutes and even hours.

Applications of Piezoelectric Instruments

Piezoelectric measuring devices are widely used today in the laboratory, on the production floor, and embedded within as original equipment. They are used in almost every conceivable application requiring accurate measurement and recording of dynamic changes in mechanical variables, such as pressure, force and acceleration. The list of applications continues to grow including:

- **Aerospace:** Modal testing, wind tunnel and shock tube instrumentation, landing gear hydraulics, rocketry, structures, ejection systems, and cutting force research
- **Ballistics:** Combustion, explosion, detonation, and sound pressure distribution
- **Biomechanics:** Multi-component force measurement for orthopedic gait and posturography, sports, ergonomics, neurology, cardiology, and rehabilitation
- **Engine Testing:** Combustion, gas exchange and injection, indicator diagrams, and dynamic stressing
- **Engineering:** Materials evaluation, control systems, reactors, building structures, ship structures, auto chassis structural testing, shock and vibration isolation, and dynamic response testing
- **Industrial/Factory:** Machine systems, metal cutting, press and crimp force, automation of force-based assembly operations, and machine health monitoring
- **OEMs:** Transportation systems, plastic molding, rockets, machine tools, compressors, engines, flexible structures, oil/gas drilling and shock/vibration testers

Piezoelectric Sensors (Quartz-Based)

The vast majority of Kistler sensors utilize quartz as the sensing element. As discussed in other sections of this catalog, Kistler also manufactures sensors which utilize piezoceramic elements and micro machined silicon structures. The discussion in this section, however, will be limited to quartz applications.

Quartz piezoelectric sensors essentially consist of thin slabs or plates cut in a precise orientation to the crystal axes depending upon the application. Most Kistler sensors incorporate a quartz element, which is sensitive to either compressive or shear loads. The shear cut is used for patented multi-component force and acceleration measuring sensors. Other specialized cuts include the transverse cut for some pressure sensors and the patented polystable cut for high temperature pressure sensors. See Fig. 1 and 2 (on next page).

Although the discussion which follows focuses on acceleration applications, the response function for force and pressure sensors has essentially the same form. In fact, many force applications are closely related to acceleration. Alternatively, pressure sensors are designed to minimize or eliminate (by direct compensation of the charge output) the vibration effect. Contact Kistler directly for more information regarding this subject.

Piezoelectric Theory

The finely lapped quartz elements are assembled either singularly or in stacks and are usually preloaded with a spring sleeve. The quartz package generates a charge signal (measured in pico Coulombs), which is directly proportional to the sustained force. Each sensor type uses a quartz configuration that is optimized and ultimately calibrated for its particular application (force, pressure, acceleration or strain). Refer to the appropriate section for important design aspects depending on the application.

Quartz sensors exhibit remarkable properties which justify their large scale use in research, development, production and testing. They are extremely stable, rugged and compact. Of the large number of piezoelectric materials available today, quartz is employed preferably in sensor designs due to the following unique properties:

- High material stress limit, approximately 150 N/mm²
- Temperature resistance up to 500 °C
- Very high rigidity, high linearity, and negligible hysteresis
- Near constant sensitivity over a wide temperature range
- Ultra-high insulation resistance

High and low impedance

Kistler supplies two types of piezoelectric sensors: high and low impedance. High impedance types have a charge output, which requires a charge amplifier or external impedance converter for charge-to-voltage conversion. Low impedance types use the same piezoelectric sensing element as high impedance types and also incorporate a miniaturized, built-in, charge-to-voltage converter. Low impedance types require an external power supply coupler to energize the electronics and decouple the subsequent DC bias voltage from the output signal.

Dynamic Behavior of Sensors

Piezoelectric sensors for measuring pressure, force and acceleration may be regarded as under-damped, spring mass systems with a signal degree of freedom. They are modeled by the classical second order differential equation whose solution is:

$$\frac{a_o}{a_b} \cong \frac{1}{\sqrt{\left[1 - \left(\frac{f}{f_n}\right)^2\right]^2 + \left(\frac{1}{Q}\right)^2 \left(\frac{f}{f_n}\right)^2}}$$

Where:

- f_n undamped natural (resonant) frequency (Hz)
- f frequency at any given point of the curve (Hz)
- a_o output acceleration
- a_b mounting base or reference acceleration ($f/f_n = 1$)
- Q factor of amplitude increase at resonance

Quartz sensors have a Q of approximately 10 ... 40. Therefore, the phase angle can be written as:

$$\text{phase lag (deg)} \cong \frac{60}{Q} \left(\frac{f}{f_n}\right) \text{ for } \frac{f}{f_n} \leq \frac{2}{5}$$

A typical frequency response curve is shown in Fig. 3. As shown, about 5 % amplitude rise can be expected at approximately 1/5 of the resonant frequency (f_n). Low-pass (LP) filtering can be used to attenuate the effects of this. Many Kistler signal conditioners (charge amplifiers and couplers) have plug-in filters designed for this purpose.

Piezoelectric Theory

Charge Amplifiers

Basically the charge amplifier consists of a high-gain inverting voltage amplifier with a MOSFET or J-FET at its input to achieve high insulation resistance. A simplified model of the charge amplifier is shown in Fig. 4. The effects of R_t and R_j will be discussed below. Neglecting their effects, the resulting output voltage becomes:

$$V_o = \frac{-q}{C_r} \times \frac{1}{1 + \frac{1}{AC_r} (C_t + C_r + C_c)}$$

For sufficiently high open loop gain, the cable and sensor capacitance can be neglected and the output voltage depends only on the input charge and the range capacitance:

$$V_o = \frac{-q}{C_r}$$

In summary, the amplifier acts as a charge integrator which compensates the sensor's electrical charge with a charge of equal magnitude and opposite polarity and ultimately produces a voltage across the range capacitor. In effect, the purpose of the charge amplifier is to convert the high impedance charge input (q) into a usable output voltage (V_o).

Time constant and drift

Two of the more important considerations in the practical use of charge amplifiers are time constant and drift. The time constant is defined as the discharge time of an AC coupled circuit. In a period of time equivalent to one time constant, a step input will decay to 37 % of its original value.

Time Constant (TC) of a charge amplifier is determined by the product of the range capacitor (C_r) and the time constant resistor (R_t):

$$TC = R_t C_r$$

Drift is defined as an undesirable change in output signal over time, which is not a function of the measured variable. Drift in a charge amplifier can be caused by low insulation resistance at the input (R_j) or by leakage current of the input MOSFET or J-FET.

Drift and time constant simultaneously affect a charge amplifier's output. One or the other will be dominant. Either the charge amplifier output will drift towards saturation (power supply) at the drift rate or it will decay towards zero at the time constant rate.

Many Kistler charge amplifiers have selectable time constants which are altered by changing the time constant resistor (R_t). Several of these charge amplifiers have a "Short", "Medium" or "Long" time constant selection switch. In the "Long" position, drift dominates any time constant effect. As long as the input insulation resistance (R_j) is maintained at greater than $10^{13} \Omega$, the charge amplifier (with MOSFET input) will drift at an approximate rate of 0,03 pC/s. Charge amplifiers with J-FET inputs are available for industrial applications but have an increased drift rate of about 0,3 pC/s.

In the "Short" and "Medium" positions, the time constant effect dominates normal leakage drift. The actual value can be determined by referring to the appropriate operation/instruction manual which is supplied with the unit. Kistler charge amplifiers without "Short", "Medium" or "Long" time constant selection, operate in the "Long" mode and drift at the rates listed above. Some of these units can be internally modified for shorter time constants to eliminate the effects of drift.

Frequency and time domain considerations

When considering the effects of time constant, the user must think in terms of either frequency or time domain. The longer the time constant, the better the low-end frequency response and the longer the usable measuring time. When measuring vibration, time constant has the same effect as a single pole, highpass (HP) filter whose amplitude and phase are:

$$\frac{V_o}{V_{in}} = \frac{2\pi f (TC)}{\sqrt{1 + [2\pi f (TC)]^2}}$$

$$\text{phase lead (deg)} = \arctan \frac{1}{2\pi f (TC)} \cong 80 \sqrt{\frac{V_{in} - V_o}{V_{in}}}$$

For example, the output voltage has declined approximately 5 % when fx (TC) equals 0,5 and the phase lead is 18°.

When measuring events with wide (or multiple) pulse widths the time constant should be at least 100 x's longer than the total event duration. Otherwise, the DC component of the output signal will decay towards zero before the event is completed.

Selection matrix

Other design features incorporated into Kistler charge amplifiers include range normalization for whole number output, low-pass filters for attenuating sensor resonant effects, electrical isolation for minimizing ground loops and digital/computer control of setup parameters.

Low Impedance Piezoelectric Sensors

Piezoelectric sensors with miniature, built-in charge-to-voltage converters are identified as low impedance units throughout this catalog. These units utilize the same types of piezoelectric sensing element(s) as their high impedance counterparts. Piezotron, Picotron, PiezoBeam, Ceramic Shear and K-Shear are all forms of Kistler low impedance sensors.

Piezoelectric Theory

In 1966, Kistler developed the first commercially available piezoelectric sensor with internal circuitry. This internal circuit is a patented design called Piezotron. This circuitry employs a miniature MOSFET input stage followed by a bipolar transistor stage that operates as a source follower (unity gain). A monolithic integrated circuit is utilized, which incorporates these circuit elements. This circuit has very high input impedance ($10^{14} \Omega$) and low output impedance (100Ω), which allows the charge generated by the quartz element to be converted into a usable voltage. The Piezotron design also has the great virtue of requiring only a single lead for power-in and signal-out. Power to the circuit is provided by a Kistler coupler (power supply), which supplies a source current (2 ... 18 mA) and energizing voltage (20 ... 30 VDC). Certain (extreme) combinations of other manufacturer's supply current and energizing voltage (i.e. 20 mA and 18 VDC, respectively), together with actual bias level, may restrict operating temperature range and voltage output swing. Contact Kistler for details. Connection is as shown in Fig. 5. A Kistler coupler and cable is all that is needed to operate a Kistler low impedance sensor.

The steady-state output voltage is essentially the input voltage at the MOSFET gate, plus any offset bias adjustment. The voltage sensitivity of a Piezotron unit can be approximated by:

$$V_o \cong \frac{q}{C_q + C_r + C_G}$$

The range capacitance (C_r) and time constant resistor (R_t) are designed to provide a predetermined sensitivity (mV/g), as well as upper and lower usable frequency. The exact sensitivity is measured during calibration and its

value is recorded on each unit's calibration certificate. Since its invention, the Piezotron design has been adapted by manufactures worldwide and has become a widely used standard for the design of sensors, which measure acceleration, force and pressure. The concept has become known by many names besides Piezotron, such as low impedance or voltage mode. A number of "brand names" have emerged by other manufactures.

Picotron is a miniature accelerometer whose circuitry is very similar to the Piezotron. PiezoBeam incorporates a bimorph ceramic element and a miniature hybrid charge amplifier for the charge-to-voltage conversion. K-Shear is the newest member of the Kistler low impedance family, which utilizes a shear quartz ele-

ment together with the Piezotron circuitry.

Time constant

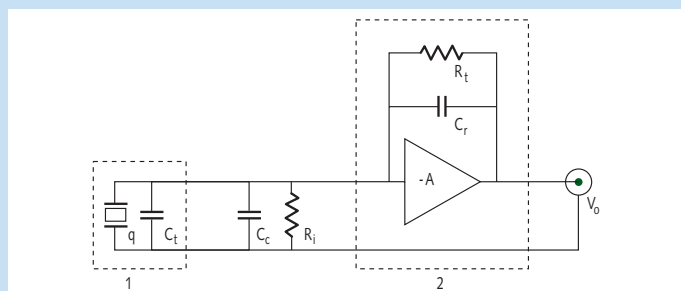

The time constant of a Piezotron or Picotron sensor is:

$$TC = R_t (C_q + C_r + C_G)$$

A PiezoBeam time constant is the product of its hybrid charge amplifier's range capacitor and time constant resistor. Time constant effects in low impedance sensors and in charge amplifiers are the same. That is, both act as a single pole, high-pass filter as discussed previously.

Capacitive Accelerometer Theory

The fundamental principle of operation for a capacitive accelerometer is the property that a repeatable change in capacitance exists when a sensing structure is deflected due to an imposed acceleration.

The acceleration creates a force (F) acting on a suspended flexure of known mass (m). The flexure moves predictably and in a controlled manner dictated by its stiffness (k). A gas-filled gap exists between surrounding electrodes, as shown in Fig. 1. The inertial force can be calculated from Newton's Second Law of Motion as:

$$F = ma \quad [\text{Eq. 1}]$$

Knowing the force, a displacement of the flexure can be estimated using a simple spring calculation:

$$x = F/k \quad [\text{Eq. 2}]$$

However, in practice, Finite Element Analysis (FEA), is employed to model the complicated spring designs. This displacement alters the gaps on either side of the flexure in an equal but opposite proportion. The distance between the flexure and surrounding electrodes (l) is then the nominal [zero g] spacing (d) ± the spring deflection (x) or:

$$l_1 = d + x \quad \& \quad l_2 = d - x \quad [\text{Eq. 3}]$$

Knowing the electrode area (A) and the permittivity constant of the gas (E), the capacitance formed by the gaps can be determined from:

$$C_1 = A \epsilon / l_1 \quad \& \quad C_2 = A \epsilon / l_2 \quad [\text{Eq. 4}]$$

This capacitance difference causes an imbalance in a bridge network of the internal electronic circuit. Internal signal conditioning incorporates AC excitation and synchronous demodulation. In addition, it provides power for the accelerometer element and outputs an analog voltage proportional to the acceleration signal.

The key operating principle of Fig. 2 is that a variable capacitive element unbalances a bridge relative to applied acceleration. The electronic action is summarized as follows:

- A voltage regulator stabilizes the accelerometer sensitivity and assures internal functions remain constant despite the supply voltage level
- A square wave generator produces excitation for the bridge circuit
- A capacitive bridge produces two signals with amplitudes relative to the applied acceleration
- The opposing signals are summed by the synchronous demodulator to form a voltage proportional to applied acceleration
- A pre-amplifier provides gain
- A built-in, low-pass filter attenuates unwanted signals above the operating frequency range

Kistler micro-machined K-Beam accelerometer sensing elements consist of very small inertial mass and flexure elements chemically etched from a single piece of silicon. The seismic mass is supported by flexure elements between two plates, which act as electrodes. As the mass deflects under acceleration, the capacitance between these plates changes. Under very large accelerations (or shocks), the motion of the mass is limited by the two stationary plates, thereby limiting the stress placed on the suspension and preventing damage. The typical design is shown in Fig. 3.

The damping of the mass by an entrapped gas creates a "squeeze film" providing an optimized frequency response over a wide temperature range. Additionally, its differential capacitive design assures immunity to thermal transients. The affect of damping is shown in Fig. 4a and appropriate damping is tuned with a specific spring mass system to achieve optimal frequency response (Fig. 4b).

Glossary

Bias voltage

DC (no load or quiescent) output level of a low impedance sensor powered by constant current excitation.

Ceramic Shear

Kistler piezoelectric accelerometer family which utilizes ceramic shear sensing elements.

Charge amplifier

Part of a measuring chain which converts the charge signal from the sensor into a proportional voltage signal or current signal.

Charge output

Output in pico Coulombs (pC) from a piezoelectric sensor without a built-in charge-to-voltage converter (see 'High impedance').

Circuit integrity indication

A quick-look reference on couplers or dual mode charge amplifier for identifying whether a low impedance system has the proper bias voltage. Analog meters and multi-color LEDs are the most commonly used indicators.

Constant current excitation

Method of powering low impedance sensors to insure minimal sensitivity variation over a wide voltage range. A Piezotron® coupler or any other IEPE type power supply may be used for this purpose.

Coupler

Electronic unit which supplies constant current excitation to low impedance sensors and decouples the subsequent bias voltage.

Crosstalk

Signal at the output of a sensor, produced by a measurand acting on the sensor, which is different from the measurand assigned to this output. For example, when a load in the F_y direction produces an F_z signal in a three-component sensor.

In terms of electrical devices, it is a measure for the signal impact acting from a channel to the neighboring ones.

Drift

Unwanted changes in the output signal independent of the measurand as a function of time.

Dual mode

Refers to a charge amplifier which can be used either with high impedance, charge output or with low impedance, voltage output sensors.

Ground isolation

High electrical resistance of a sensor between signal line and ground, or of a charge amplifier between connector screen and ground.

High impedance

Another term for a piezoelectric sensor with charge output (i.e. pC/mechanical unit).

Hysteresis

The maximum difference in output, at any measurand value within the specified range, when the value is approached first increasing and then decreasing measurand (source: ANSI/ISA-S37.1).

Note: The quartz crystal itself has a scarcely measurable hysteresis. However, the mechanical construction of the sensor can result in slight hysteresis. If the hysteresis is above the specified values (in %FSO), then the sensor is faulty or has not been correctly installed.

IEPE

Integrated Electronic PiezoElectric (see Piezotron®).

Impedance converter

A miniature electronic unit with MOSFET input and bipolar output for converting high impedance, charge outputs (from a sensor) into low impedance, voltage outputs. Impedance converters can be built into the sensor (see 'Low impedance') or can be used externally for special applications.

Impedance head

Sensor that simultaneously measures both force and acceleration during modal analysis testing.

Insulation resistance

Electric resistance of a sensor, cable or the input of a charge amplifier measured between the signal line and the connection ground (sensor body), while the test voltage is stated accordingly. The insulation resistance applies for piezoelectric sensor, strain gauge sensors and semiconductor sensors.

K-Beam®

Kistler's solid-state, variable capacitance based line of accelerometers, which are suitable for measuring low frequencies or even steady-state conditions.

K-Shear®

Kistler's piezoelectric accelerometer family. Low impedance accelerometer that utilizes quartz shear sensing element.

Linearity

Linearity is defined as the closeness of the calibration curve to a specified line (source: ANSI/ISA-S37.1).

Linearity represents the maximum deviation between ideal and actual output signal characteristics in relation to the measurand in a specific measuring range. It is expressed in percentage of the range of measurement signal (full-scale output). Note: Quartz crystals produce an electric charge, which is exactly proportional to the load. However, unavoidable deviations occur due to the mechanical construction of the sensor.

Low impedance

Another name for a piezoelectric sensor with a miniature, built-in charge to voltage converter. Output is typically in mV/mechanical unit. K-Shear®, Piezotron®, Picotron and PiezoBeam® are all forms of low impedance sensors.

Low-pass filter

Special type of filter that high frequency components of a measurement signal hides (electronic, mechanical, digital).

Measurand

Physical quantity, state or characteristic which is measured, e.g. force, torque, pressure, etc.

Glossary

Natural frequency

Frequency of free (not forced) oscillations of the entire sensor. In practice, the (usually lower) natural frequency of the entire mounting structure governs the frequency behavior.

Newton (N)

The metric unit of force measurement equivalent to 1 kg m s⁻² or 0.2248 lbf.

pico Coulomb (pC)

A unit of electrical charge equivalent to 1x10⁻¹² ampere second.

Picotron

Mini accelerometer with Piezotron circuitry.

PiezoBeam®

Low impedance accelerometer; incorporates a bimorph ceramic element that generates an electrical charge when mechanically loaded.

Piezoelectric sensor

Sensor with element that generates an electrical charge when mechanically loaded.

PiezoStar®

Kistler proprietary crystal used with IEPE accelerometers to provide ultra-low sensitivity shift with temperature.

Piezotron®

Patented Kistler piezoelectric sensors with miniature, built-in impedance converters (see 'Impedance converter').

Polystable®

Patented Kistler quartz element incorporated into pressure sensor designs for operating temperatures up to 350 °C.

Quasi-static

Describes the ability of Kistler sensors, charge amplifiers, and electrical devices to undertake time-variable and nearly time constant measurements (e.g. long-term measurements or DC-similar measurements).

Resonance frequency

Resonance frequency corresponds the frequency of an oscillating system, at which a resonance case is observed. Frequencies are called resonance frequencies of a system, when the amplitude of a system oscillation responds with a local maximum at constant excitation (forced oscillation).

Rise time

The length of time for the output of a sensor to rise from 10 % to 90 % of its final value as a result of a step-change of measurand.

Sealing

The degree of sealing as per EN 60529 is IP66 (commonly denoted as 'epoxy' sealing) IP67 ('epoxy/welded'), and IP68 ('hermetic').

Sensitivity

Nominal value or calibrated value stated in the calibration certificate of the change in the response of a sensor divided by the corresponding change in the value of the measurand.

TEDS

Transducer Electronic Data Sheet. Characteristic data stored digitally internal to sensor, IEEE 1451.4 compliant.

TEDS Versions

T	Default, IEEE 1451.4 V0.9 Template 0 (UTID 1)
T01	IEEE 1451.4 V0.9 Template 24 (UTID 116225)
T02	LMS Template 117, Free format Point ID
T03	LMS Template 118, Automotive Format (Field 14 Geometry = 0)
T04	LMS Template 118, Aerospace Format (Field 14 Geometry = 1)
T05	P1451.4 v1.0 template 25 - Transfer Function Disabled
T06	P1451.4 v1.0 template 25 - Transfer Function Enabled

Temperature coefficient of sensitivity

Change in the sensitivity, i.e. the slope of the best straight line, as a function of temperature. The temperature distribution in the sensor is assumed to be homogeneous, and in thermal equilibrium with the environment. PiezoStar® sensors boast very low temperature coefficient of sensitivity (typically %/°C).

Time constant (TC)

The time constant describes the behavior of a high-pass filter and represents the time after which the signal is reduced to 1/e of the output value.

Note: The time constant enables the measuring error to be estimated in relation to the measuring duration. You will find detailed information on time constants and sensitivity ranges in the operating instructions for your charge amplifier. Example: The time constant depends on the measuring range selected on the charge amplifier. Possible values vary from approx. 0,01 s in the most sensitive range to approx. 100 000 s in the least sensitive range. The largest possible time constant must be selected for quasi-static measurements.

Threshold

Largest change in the measurand that produces a measurable change in the sensor output, while the change of the measurand takes place slowly and monotonically.

Note: In practice, the rule of thumb applies that the threshold is about two to three x's as large as the typical noise signal of a charge amplifier. This value can, however, only be achieved in dynamic measurements, whereas with quasi-static measurements, drift and environmental influences are limiting factors.

Transverse sensitivity

The output of an accelerometer caused by acceleration perpendicular to the measuring axis.

Voltage output

Output (in mV) from a piezoelectric sensor with a built-in charge-to-voltage converter (see 'Low impedance').
